

Python Inbuilt Functions:

Sure, here are 10 more examples of built-in functions in Python and how they can be used:

1. `chr()`:

```
```python
print(chr(97))
```
```

This will output the character corresponding to the ASCII code 97, which is "a".

2. `ord()`:

```
```python
print(ord('a'))
```
```

This will output the ASCII code for the character 'a', which is 97.

3. `bin()`:

```
```python
print(bin(5))
```
```

This will output the binary representation of the integer 5, which is "0b101".

4. `hex()`:

```
```python
print(hex(15))
```
```

This will output the hexadecimal representation of the integer 15, which is "0xf".

5. `abs()`:

```
```python
print(abs(-5))
```
```

This will output the absolute value of -5, which is 5.

6. `len()`:

```
```python
list1 = [1, 2, 3, 4, 5]
print(len(list1))
```
```

This will output the length of the list, which is 5.

7. `type()`:

```
```python
x = 5
print(type(x))
```
```

This will output the data type of x, which is `<class 'int'>`.

8. `str()`:

```
```python
x = 5
print(str(x))
```
```

This will convert the integer x into a string and output "5".

9. `float()`:

```
```python
x = "3.14159"
print(float(x))
```
```

This will convert the string x into a floating-point number and output 3.14159.

10. `zip()`:

```
```python
list1 = [1, 2, 3]
list2 = ['a', 'b', 'c']
result = zip(list1, list2)
print(list(result))
```
```

This will combine the lists `list1` and `list2` into a list of tuples and output `[(1, 'a'), (2, 'b'), (3, 'c')]`.

Sure, here are 5 more examples of built-in functions in Python and how they can be used:

1. `enumerate()`:

```
```python
fruits = ['apple', 'banana', 'cherry']
for i, fruit in enumerate(fruits):
 print(i, fruit)
```
```

This will output the index and value of each element in the list, like so:

```
```
0 apple
1 banana
2 cherry
```
```

2. `all()`:

```
```python
numbers = [2, 4, 6, 8, 10]
result = all(num % 2 == 0 for num in numbers)
print(result)
```
```

This will check if all the numbers in the list are even and output `True`.

3. `any()`:

```
```python
numbers = [1, 2, 3, 4, 5]
result = any(num % 2 == 0 for num in numbers)
print(result)
```
```

This will check if any of the numbers in the list are even and output `True`.

4. `abs()`:

```
```python
```

```
print(abs(-5))
'''
```

This will output the absolute value of -5, which is 5.

5. `.format()`:

```
'''python
name = "Alice"
age = 25
print("My name is {} and I am {} years old.".format(name, age))
'''
```

This will format the string with the values of `name` and `age`, outputting `My name is Alice and I am 25 years old.`

These are just a few more examples of built-in functions in Python. There are many more built-in functions available in Python that can be used for a variety of tasks.
